

Organ support in ACLF – non PLEX systems

Lee Kang Hoe

Associate Professor, NUS Yong Loo Lin School of Medicine

Definitions of ACLF

CULLARD ET AL.

LIVER TRANSPLANTATION, February 2020

FIG. 2. Characteristics of major definitions of ACLF.³¹⁻³⁶ High-risk organ failure includes renal failure or other organ failure with either renal or cerebral dysfunction.

Extrahepatic and intrahepatic insults

TABLE 1. Precipitants of ACLF with Percentages Reported in Large Databases

	Europe	North America	Asia
Precipitating factors			
Extrahepatic			
Infection	53	—	38
GI hemorrhage	13	—	10
Procedures (TIPS, LRT, ECP)	9-11	—	2
Intrahepatic			
Viral hepatitis	45	—	36
Alcohol	25	—	6
DILI	—	—	11
Autoimmune disease	—	—	2
Not identifiable	22	—	20
More than 1 factor	14	—	9
Underlying etiology of cirrhosis			
Viral	18	52	62
Alcohol	67	42	20
Cryptogenic	3	15	7
Miscellaneous	8	18	4

NOTE: Data are given as percentages and are from Morano et al.,⁽²⁾ Bajaj et al.,⁽³⁾ Cholongitas et al.,⁽¹³⁾ Waijler et al.,⁽¹⁴⁾ Xia et al.,⁽¹⁵⁾ and Shi et al.⁽¹⁶⁾

ACLF – organ failure (s)
(usually kidney) plus
systemic inflammation,
associated with increasing
mortality coupled to the
number of organ failures

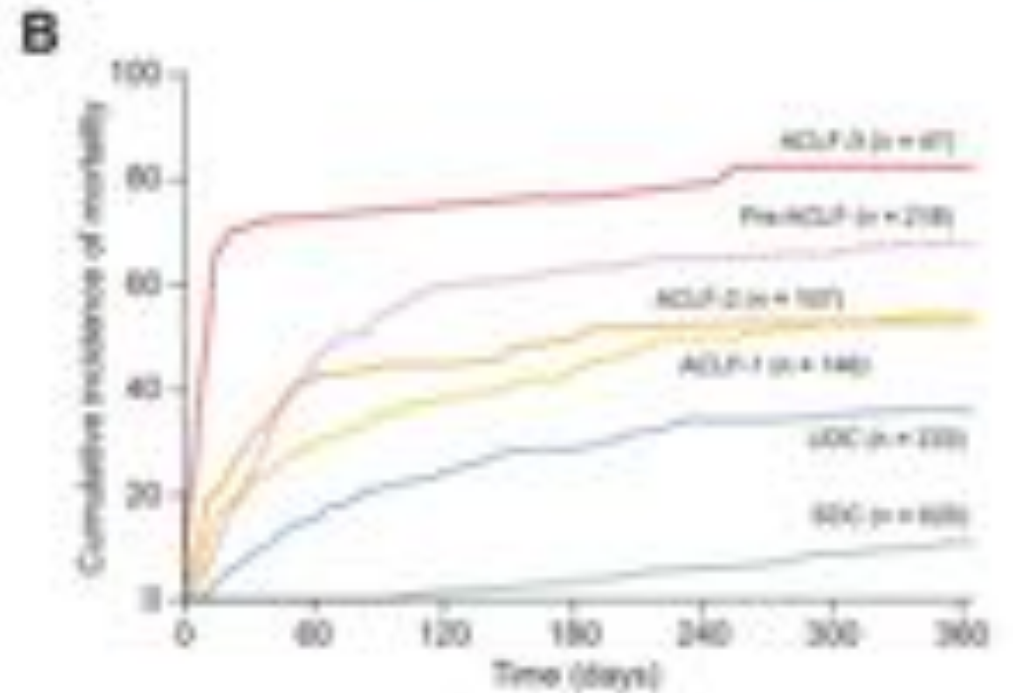

Fig. 1. Clinical trajectory of patients with cirrhosis. (B) Shows that patients can suffer either from acute decompensation, which implies need for hospitalisation with an acute liver-related complication or a less well-defined entity, called non-acute decompensation, which refers to the occurrence of a progressive liver-related complication that does not lead to hospitalisation. Patients with acutely decompensated cirrhosis without ACLF at presentation can be retrospectively classified into three distinct groups according to the three distinct disease trajectories during the 3 months after admission. Patients can be categorised as having SOC (patients in this group were discharged and not readmitted during the 3-month follow-up), UOC (patients in this group developed liver-related complications, but not ACLF, and were readmitted during the 3-month follow-up), or pre-ACLF (because patients in this group developed ACLF during the 3-month follow-up). Patients who present with ACLF meet criteria for one of three grades of ACLF. Overall, patients with acutely decompensated cirrhosis may therefore be divided into six distinct groups. Modified from Jalan et al.¹¹¹ and O'Leary et al.¹¹² (B) shows the outcomes of the six groups (Reproduced from¹¹¹). ACLF, acute-on-chronic liver failure; SOC, stable decompensated cirrhosis; UOC, unstable decompensated cirrhosis.

Table 3. Prognostic scoring systems^{12,34}

(A) CLIF-SOFA Score

Organ/system	0	1	2	3	4
Liver (bilirubin, mg/dL)	<1.2	≥1.2 to <2.0	≥2.0 to <6.0	≥6.0 to <12.0	≥12.0
Kidney (creatinine, mg/dL)	<1.2	≥1.2 to <2.0	≥2.0 to <3.5	≥3.5 to <5.0	≥5.0
or use of renal replacement therapy					
Cerebral (HE grade)	No HE	I	II	III	IV
Coagulation (international normalized ratio)	<1.1	≥1.1 to <1.25	≥1.25 to <1.5	≥1.5 to <2.5	≥2.5 or platelet count <20×10 ⁹ /L
Circulation (mean arterial pressure, mm Hg)	≥70	<70	Dopamine ≤5 or dobutamine or terlipressin	Dopamine >5 or E ≤0.1 or NE ≤0.1	Dopamine >15 or E >0.1 or NE >0.1
Lungs					
P _a O ₂ /F _i O ₂ or	>400	>300 to ≤400	>200 to ≤300	>100 to ≤200	≤100
SpO ₂ /F _i O ₂	>512	>357 to ≤512	>214 to ≤357	>89 to ≤214	≤89

CLIF C-ACLF score $10 \times [0.033 \times \text{Clif OFs} + 0.04 \times \text{Age} + 0.63 \times \ln(\text{WBC}) - 2]$.

CLIF C-ACLF, chronic liver failure consortium acute-on-chronic liver failure; HE, hepatic encephalopathy; NE, nor epinephrine; WBC, white blood cell count.

(B) AARC Score

Points	Total bilirubin (mg/dL)	HE grades	INR	Lactate (mmol/L)	Serum creatinine (mg/dL)
1	<15	0	<1.8	<1.5	<0.7
2	15–25	I–II	1.8–2.5	1.5–2.5	0.7–1.5
3	>25	III–IV	>2.5	>2.5	>1.5

AARC score in ACLF grade 1=5–7, grade 2=8–10, grade 3=11–15.

INR, international normalized ratio; HE, hepatic encephalopathy; ACLF, acute-on-chronic liver failure; APASL, Asian Pacific Association for Study of Liver; AARC, APASL ACLF research consortium.

Role of ammonia in predicting the outcome of patients with acute-on-chronic liver failure

Chiriac et al. World J Clin Cases. 2021 Jan 26; 9(3): 552–564

- 456 pts with ACLF
- Receiver operating characteristic analysis showed good accuracy for the prediction of in-hospital mortality for the AARC score [Area under the curve (AUC) = 0.886], MELD score (AUC = 0.816), VA (venous ammonia) (AUC = 0.812) and a fair accuracy for the Child-Pugh score (AUC = 0.799).
- Subsequently, a cut-off value for the prediction of mortality was identified for **VA (152.5 $\mu\text{mol/L}$)**, sensitivity = 0.706, 1-specificity = 0.190).
- Univariate analysis found acute kidney injury, severe HE (grade III or IV), VA $\geq 152.5 \mu\text{mol/L}$, MELD score ≥ 22.5 , Child-Pugh score ≥ 12.5 , and AARC score ≥ 8.5 to be associated with in-hospital mortality.
- Multivariate analysis identified AARC score ≥ 8.5 and venous ammonia $\geq 152 \mu\text{mol/L}$ to be independent predictors of in-hospital mortality.

Liver transplantation in the most severely ill cirrhotic patients: A multicenter study in acute-on-chronic liver failure grade 3

Artu et al. J Hepatology 2017

Fig. 2. One-year survival of patients transplanted with ACLF-3 and of non-transplanted matched controls with cirrhosis and multiple organ dysfunction. The 1-year survival rate was much higher in the transplanted patients than in controls; 83.6% (95% CI: 75-92) vs. 1.8% (95% CI: 2.8-12.5) with an HR for mortality of 0.07 (95% CI: 0.01-0.11; $p < 0.0001$). The 1-year survival of ACLF-3 case was compared with the control group by Cox regression models using a robust sandwich covariance matrix to account for the matched set.

Questions for organ support in ACLF ?

- Removal of cytokines (DAMPS) / endotoxin???
- Improves renal function ?
- Improves hepatic encephalopathy
- Removes ammonia ?
- Removes bilirubin ?
- Improves hemodynamics ?
- Lung function ?
- Coagulation ?
- Outcome / Better survival ?

We believe that:

- 1. High ammonia is BAD**
- 2. Reducing HE grade is desirable**
- 3. Supporting renal function**
- 4. Removing cytokines is probably good**
- 5. We would like to have better outcomes by transiting pt to liver transplant in the best condition**

Extracorporeal liver support systems

- Biological – contains liver cells (human or animal)
 - Circe (porcine)
 - ELAD (hepatoblastoma cell line)
- Non biological systems
 - Plasmapheresis
 - Albumin dialysis (MARS)
 - Prometheus - a combination of direct adsorption of albumin bound toxins to an adsorber and the removal of water-soluble toxins by high-flux dialysis
 - CRRT with various filters (Hemodiafiltration versus hemodialysis)
 - Adsorption devices (Charcoal, Cytosorb, Jafron, Oxiris, Dialive)
 - ADVOS (Advanced organ support) – multiple combined function

Extracorporeal Liver Assist Device (ELAD)

Cartridges with the liver cells (C3A)

ELAD treatment consisted of drawing blood from the subject via a dual-lumen catheter using an extracorporeal pumping unit and then separating the plasma fluid (ultrafiltrate [UF]) from the cellular components using a specifically designed UF generator cartridge. While the cellular components are returned to the subject via the venous access, the UF is circulated at a high flowrate through 4 metabolically active hollow-fiber ELAD cartridges containing approximately 440 g of C3A cells. After circulation through the cartridges, the UF passes through a 0.2-mm pore-size filter, is recombined with the cellular components of the subject's blood, and is returned to the subject through the dual-lumen catheter

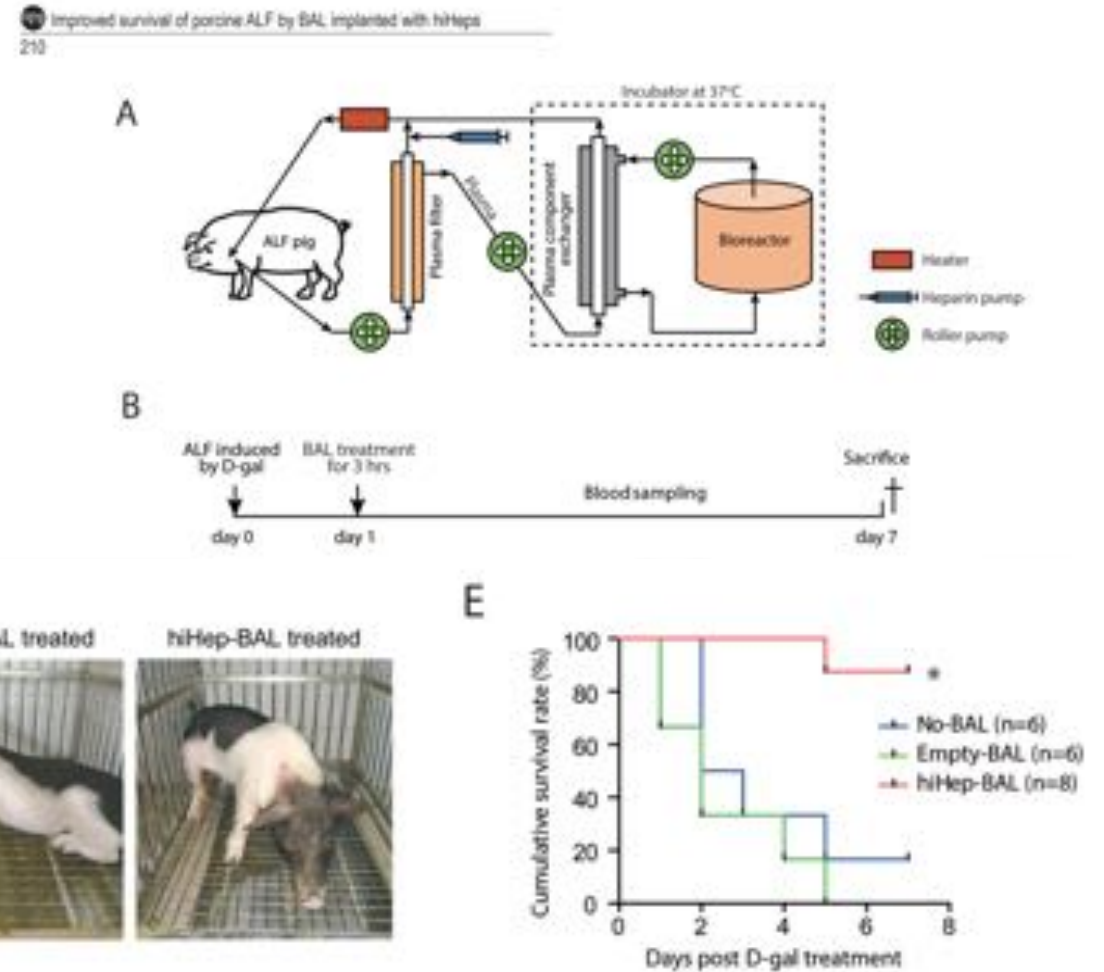

Extracorporeal Cellular Therapy(ELAD) in Severe Alcoholic Hepatitis: A Multinational, Prospective, Controlled, Randomized Trial

Liver Transplantation 24 380–393 2018

Improved survival of porcine acute liver failure by a bioartificial liver device implanted with induced human functional hepatocytes.

Cell Research (2016) 26:206-216.

- We previously generated human functional hepatocytes by lineage conversion (hiHeps).
- Here, by improving functional maturity of hiHeps and producing hiHeps at clinical scales (3 billion cells), we developed a hiHep-based BAL system (hiHep-BAL).
- In a porcine ALF model, hiHep-BAL treatment restored liver functions, corrected blood levels of ammonia and bilirubin, and prolonged survival.
- Importantly, human albumin and α -1-antitrypsin were detectable in hiHep-BAL-treated ALF pigs.
- Moreover, hiHep-BAL treatment led to attenuated liver damage, resolved inflammation and enhanced liver regeneration.

What are we trying to remove in our ACLF pt?

- 55 year female with MELD 18 chronic hep B presents with fever and hypotension and abdominal pain
- Bilirubin was 300 umol/L. INR was 3, ammonia was 200 umol/L and creatinine was 250 umol/L
- Blood culture was positive for gram negative rods, and ascites on examination with HE grade 3.
- Diagnosis was SBP with septic shock and ACLF.
- We would like to improve:
 - Reduce ammonia levels and hopefully improve HE
 - Treat septic shock
 - Support renal failure
 - Maybe reduce bilirubin and support INR

Chemistry

- Ammonia:
 - Small molecule (smaller than water). Removal correlates with urea clearance.
 - 17 daltons
 - Water soluble
- Bilirubin, being insoluble in an aqueous solution, is carried in circulation bound to albumin which is a reversible and covalent type of bonding.

Basis for “dialysis” – setup is important

- “Wastes” (Solutes) and excess water are removed by using an external filter called a dialyzer, which contains a semipermeable membrane. The separation of wastes is done by creating a counter-current flow gradient, where blood flow is in one direction and the fluid of the dialyzer is in the opposite direction
- Diffusion
- Osmosis
- Ultrafiltration
- Net removal of solutes is influenced by: (1) the concentration gradient for diffusion, (2) the diffusivity of the solute, (3) permeability characteristics and surface area of the membrane, (4) blood and dialysate flow within the dialyzer, (5) the duration of dialysis, (6) the distribution volume of the solutes, and (7) amount of ultrafiltration (convective transfer).

Setup for CRRT

- Vascular access – may influence blood flow rates
- Orders require:
 - Modality (CVVH, CVVHD or CVVHDF (convective clearance))
 - Blood flow
 - Dialysate flow rate
 - Type of dialysate and type of replacement fluid
 - Replacement fluid (pre or post filter)
 - Ultrafiltration
 - Dialyzer (biocompatible membrane, high flux (pore size), high permeability ?)
 - Anticoagulation
 - Duration
 - Additional cartridge (e.g. Cytosorb)

Dialyzer

- The utilized membranes are classified into two main groups:
 - low-flux, which is based on using dialyzers with low permeability for water; and
 - high-flux, non-celluloses membrane with increased permeability, which is capable of removing moderate-sized molecules between 10000 to 15000 Dalton, including many of the inflammatory proteins, β_2 microglobulin and lipoproteins
- High flux dialysers are 'leakier' dialysers .. and that holds true for bi-directional membrane transit. This means that not only can more and larger solutes be removed from the patient—but at least potentially, more water-borne contaminants, e.g. endotoxin, can get in!
- Also need bicarbonate dialysate

Ammonia

- Ammonia clearance was increased by either higher dialysate flow rate (DFR) or ultrafiltration rate (dialysis dose), a higher blood flow rate (BFR), and removal by a longer duration of treatment. There was a moderate correlation between ammonia clearance and EFR.

Table 2. Ammonia clearance and ammonia clearance according to ultrafiltration dose: 10 vs 30 mL/h

Parameter	Low volume 10 mL/h n = 13	High volume 30 mL/h n = 13	P value
Baseline	280 (200-380)	280 (200-380)	0.994
Infused	2.280 (1.400-2.700)	2.000	<0.001
Clearance	12.1	1.6	<0.001
(L/24 h/1.73 m ²)			
Ammonia clearance	30 (24-36)	30 (24-36)	0.999
Infused	30 (24-36)	30 (24-36)	0.999
Ammonia clearance	30 (24-36)	30 (24-36)	0.999
Infused	30 (24-36)	30 (24-36)	0.999
Ammonia clearance	30 (24-36)	30 (24-36)	0.999
Infused	30 (24-36)	30 (24-36)	0.999

df, degrees of freedom

Fig. 3. Correlation between ultrafiltration rate and ammonia clearance after 1 h of continuous renal replacement therapy.

Fig. 4. Changes in plasma ammonia concentration after 1 and 2 h after the initiation of continuous renal replacement therapy. Intra-hospital ammonia clearance is similar to inter-hospital ammonia clearance.

Fig. 5. Correlation between ammonia clearance and ammonia clearance using continuous ammonia replacement.

Extracorporeal Ammonia Clearance for Hyperammonemia in Critically Ill Patients: A Scoping Review

Blood Purif 2021;50:453–461

Fig. 2. Ammonia clearance according to CRR and BCR. **a** Ammonia clearance according to CRR. **b** Ammonia clearance according to BCR. CRR, continuous renal replacement therapy; BCR, intermittent hemodialysis; EFR, effluent flow rate; BFR, blood flow rate.

Ammonia clearance was increased by either higher dialysate flow rate (DFR) or ultrafiltration rate (dialysis dose), a higher blood flow rate (BFR), and removal by a longer duration of treatment

Correction and Control of Hyperammonemia in Acute Liver Failure: The Impact of Continuous Renal Replacement Timing, Intensity, and Duration.

Warillow et al. Crit Care Med Feb 2020

Figure 1. Ammonia dynamics over 5 d of treatment with continuous renal replacement therapy in acute liver failure. $p < 0.0001$. Geometric means of log transformed data. Error bars indicate 95% CI.

Details of CRRT Management	Characteristics	Patients (n/N)
Timing of CRRT, n/N (median IQR)	Time from admission to CRRT	40 (23-43)
	Cumulative duration of CRRT	74 (57-79)
CRRT mode, n/N	Continuous venovenous hemofiltration	40 (78)
	Continuous venovenous hemodiafiltration	12 (22)
Blood flow, mL/min, n/N	Blood flow 200	31 (64)
	Blood flow 250	3 (6)
	Blood flow 300	7 (14)
Ultrafiltration volume, mL/hr, n/N	Ultrafiltrate rate 1000	15 (34)
	Ultrafiltrate rate 1500	19 (39)
	Ultrafiltrate rate 4000	18 (36)
	Ultrafiltrate rate 5000	9 (18)
CRRT dosing, mL/kg/hr, median IQR	CRRT hourly rate	40 (27-47)
Anticoagulation during CRRT, n/N	No anticoagulation	30 (67)
	Unfractionated heparin	1 (2)
	Unfractionated heparin + protamine (heparin)	10 (19)
	Unfractionated heparin + apixiban	9 (17)
	Citrate (heparin)	1 (2)

CRRT = continuous renal replacement therapy; IQR = interquartile range. Cumulative dosing on CRRT up to day 5 of ICU admission (i.e., cumulative dose in ICU prior to CRRT commencement and time after CRRT first initiation as well as intervals between treatments that were interrupted by technical problems, flow ceiling, and patient initiation in sedation, operating room, and laboratory). The number of patients who received CRRT on each ICU day and withdrew day 1 to day 5 is: day 1: 10; day 2: 34; day 3: 40; and day 4: 36. Data presented as median (IQR) and n/N.

85% acetaminophen
83% Grade 3 or 4
9% liver Tx
74% hospital survival

Renal dose in CRRT

- Assume complete saturation of small solutes in the effluent (Lancet 356,26–30 (2000))
- Clearance is therefore equal to **total effluent volume**

Box 1 | Assessment of dialysis dose in CRRT

CVVH

- Prescribed dose = $(Q_r + Q_{net})$
- Delivered dose = $(Q_r + Q_{net}) \times S$

CVVHDF

- Prescribed dose = $(Q_r + Q_d + Q_{net})$
- Delivered dose = $(Q_r + Q_d + Q_{net}) \times S$

Abbreviations: BUN, blood urea nitrogen; CRRT, continuous renal replacement therapy; CVVH, continuous venovenous hemofiltration; CVVHDF, continuous venovenous hemodiafiltration; FUN, effluent fluid urea nitrogen; Qd, dialysate fluid rate; Qnet, net fluid removal rate; Qr, replacement fluid rate; S, FUN/BUN ratio.

Figure 1 | The effect of concentration polarization and clotting on delivered dialysis dose. Filter efficacy declines over time; protein fouling and filter clotting occur on the membrane and decrease the surface available for diffusion or convection, which reduces the amount of dose being delivered. These important factors must be frequently monitored during continuous renal replacement therapies. Abbreviations: BUN, blood urea nitrogen; FUN, effluent fluid urea nitrogen; Qd, dialysate fluid rate; Qnet, net fluid removal rate; Qr, replacement fluid rate; S, FUN/BUN ratio.

Renal dose for ammonia clearance

The screenshot shows a medical device interface with a 'Status' header. Below the header, there are two tabs: 'Prescription' and 'Anticoagulation'. The 'Prescription' tab is active, displaying a list of parameters and their values. At the top right, patient information is shown: '716E' and '75 kg'. At the bottom right, there is an 'ADJUST' button.

Prescription	Anticoagulation
Blood	300 ml/min
Pre Blood Pump	0 ml/h
Dialysate	2000 ml/h
Replacement	3000 ml/h
	Pre
Pt Fluid Removal	0 ml/h
Effluent	5000 ml/h
Effluent Dose	67 ml/kg/h
UFR Dose	33 ml/kg/h
Filtration Fraction	19 %

Dilution factor = plasma flow rate (ml/hr)/ (plasma flow rate + pre filter replacement fluid rate).

Plasma flow rate (ml/hr) = blood flow rate (ml/min) x 60 (min/hr) X (1-hematocrit)

Example shown: Hct was 0.26

Show dilution factor = $300 \times 60 \times 0.74 / ((300 \times 60 \times 0.74) + 3000) = \mathbf{0.727}$

Actual dose = (Effluent dose x dilution factor)/ weight = $(5000 \times 0.727) / 75 = \mathbf{\underline{48.5 \text{ ml/kg/hr}}}$

Assuming sieving coefficient of urea is 1

Adsorption options

- Charcoal hemoperfusion
- Oxiris
- Jafron
- Cytosorb

Hemoperfusion is the method by which blood is cleared of various compounds by directly perfusing it over a sorbent bed or column, which have a binding affinity for the substances to be removed. The sorbent used may be activated charcoal, non-ionic or ionic resins, or immunosorbents. Adsorption of the solute to the sorbent is based on chemical affinity, rather than molecular size.

Removal of Cytokines and Endotoxin and may benefit vasoplegic shock

Also utilized in septic shock and severe ARDS

ORDERING INFORMATION	

The oXiris set has a unique, proprietary three-layer membrane structure: The base AN69 membrane enables absorption of cytokines and toxins while providing efficient renal support by diffusion and convection. The PEI (polyethyleneimine) surface treatment allows for the adsorption of endotoxins while the removal of fluid and toxins (CRRT) occurs throughout the entire membrane. The heparin graft on the membrane reduces membrane thrombogenicity and is designed to minimize treatment interruptions while supporting adequate dialysis dose delivery

Surface Area for Oxiris 1.5 m² vs m100 0.9 m²

It is a 300 mL container filled with biocompatible, highly porous polystyrene divinylbenzene beads that form a large surface of about 45,000 m², adsorbing hydrophobic molecules up to approximately 55 kDa. As most cytokines fall within this range, the device is potentially capable of eliminating toxic substances rapidly from the blood.

Haemoadsorption by CytoSorb® in patients with acute liver failure: A case series

Dana Tomescu^{1,2}, Mihai Popescu^{1,2} , Corina David²,
Romina Sima¹  and Simona Dima¹

Abstract

Acute liver failure (ALF) is a life-threatening disease associated with multi-organ failure and increased mortality. Severe inflammation is now considered the main pathophysiological mechanism for organ dysfunction, thus rebalancing pro- and anti-inflammatory cytokines may improve liver function and outcome. The aim of this study was to assess the clinical effects of a haemoadsorption column on biochemical parameters in patients with ALF. We prospectively included 18 patients with ALF who were treated with three consecutive sessions of continuous venovenous haemofiltration in combination with CytoSorb®. Our results show an improvement in liver functional tests and a decrease in C-reactive protein. Thrombocytopenia remains one of the most important side effects of this treatment and careful consideration should be made before initiation of treatment.

The cytokine adsorber Cytosorb® does not reduce ammonia concentrations in critically ill patients with liver failure.

Intensive Care Med 2023

Albumin based extracorporeal blood purification (SPAD, MARS, Prometheus, DIALIVE and ADVOS)

MARS™ Currently The Most Widely-used System

- Molecular Adsorbents Recirculating System
- Developed at the University of Rostock, Germany – currently owned by Gambro.
- Hollow fibred dialyzer with albumin impregnated polysulfone membrane with a pore size of 50 kD.
- Constant flow of albumin-rich (20%) dialysate (600mL) in the extracapillary compartment. Recirculation.
- Removal of protein bound molecules (like bilirubin) and water soluble toxins

SPAD – Single Pass Albumin Dialysis.

Just add albumin to the dialysis and discard after single pass!

For instance, dialysate usage of 2 l/hr (to achieve ~ 25 ml/kg/hr effluent dose) using an albumin concentration of 3%, results in a consumption of 1440 g/24 hours. Costly!

MARS™ (Molecular Adsorbent Recirculating System)

Wagholikar GD, Lee KH, Pandey D, Leong SO, Singh R, Tan KC. Pre-transplant optimization by molecular adsorbent recirculating system in patients with severely decompensated chronic liver disease. Indian J Gastroenterol 2007;26:110-112

May 2007 · Indian Journal of Gastroenterology
26(3):110-2

*Case #2 had HCV-related disease, #8 and 9 had cryptogenic cirrhosis, the rest had HBV-related disease. HE: grade of hepatic encephalopathy; Duration: duration in days between start of 1st MARS dialysis and LT; INR: international normalized ratio; HBV: hepatitis B virus; HCV: hepatitis C virus; POD: post-operative day; ^adata in $\mu\text{mol/L}$ (conversion of SI units: bilirubin - $\mu\text{mol/L} \times 0.0585 = \text{mg/dL}$, creatinine - $\mu\text{mol/L} \times 0.0113 = \text{mg/dL}$). @: data as number of sessions

The outcome of liver transplantation (LT) is influenced by the recipient's clinical condition. In a retrospective observational study, we evaluated the role of pre-LT Molecular Adsorbent Recirculating System (MARS) treatment in improving the clinical status and thereby the outcome of patients with chronic liver disease and severe hepatic decompensation. Between March 2002 and September 2006, 70 patients with end-stage chronic liver disease underwent living-donor LT (LDLT). Of these, 9 (13%) patients with severely decompensated liver function (serum bilirubin > 350 $\mu\text{mol/L}$ [20 mg/dL] and/or hepatic encephalopathy > or = grade 2) received pre-LT MARS treatment. The median MELD score was 33 (range, 26-47). A median of 2 (range, 1-6) sessions (8 hour/session) of MARS dialysis was performed per patient. MARS treatment was associated with reduction in serum bilirubin, creatinine and ammonia levels and no procedure-related complications. Pre-LT MARS is well tolerated and results in reduction of jaundice and improvement in renal function and may be useful in the management of patients with severe hepatic decompensation.

Extracorporeal Albumin Dialysis With the Molecular Adsorbent Recirculating System in Acute-on-Chronic Liver Failure: The RELIEF Trial

1158 BAJAJ ET AL

HEPATOLOGY, March 2013

Fig. 2. Cumulative probability of 28-day transplant-free survival. Left panel: Intention to treat survival. Right panel: Per-protocol survival. Green line: MARS therapy plus SMT. Blue line: SMT alone. MARS: extracorporeal albumin dialysis. SMT: standard medical therapy.

At scheduled doses, a beneficial effect on survival of MARS therapy in patients with ACLF could not be demonstrated.

(HEPATOLOGY 2013;57:1153-1162)

In all, 189 patients with ACLF were randomized either to MARS (n = 95) or to standard therapy (SMT) (n = 94).

The 28-day survival was similar in the two groups in the ITT and PP populations (60.7% versus 58.9%; 60% versus 59.2% respectively).

MELD score and HE at admission and the increase in serum bilirubin at day 4 were independent predictors of death.

At day 4, a greater decrease in serum creatinine ($P = 0.02$) and bilirubin ($P = 0.001$) and a more frequent improvement in HE (from grade II-IV to grade 0-I; 62.5% versus 38.2%; $P = 0.07$) was observed in the MARS group.

Benefits From MARS™ Treatment

- Reduces bilirubin and ammonia levels
- Improves hepato-renal syndrome (HRS)
- Improves encephalopathy (reduces cerebral oedema)
- Improves hemodynamics (NO removal)
- **Improves outcome (7 day Type 1 HRS survival: 67% MARS and 0% in control; MARS-RELIEF trial – no survival benefit; French high urgency ALF pts – better transplant free 6 month survival).**
- BUT ...???
 - Reduces antibiotic levels
 - Causes hypoglycemia when glucose-free dialysate utilized
 - Pro-inflammatory

Recent US/Europe Trial on Hepatic Encephalopathy

- Multi-center (6 US and 2 Europe)
- 70 pts recruited: mean MELD 31 ± 10 ; CTP 12.7 ± 1.3 ; Age 53 ± 11 ; 56% male; 56% HE grade 3; 44% HE grade 4
- 6 hrs of MARS for 5 consecutive days
- Significant improvement in hepatic encephalopathy (2 grades or more) with MARS treatment compared to controls and more rapid improvement
- Excluded pts with renal failure

Table 4. Percentage of Patients Showing a Response to Treatment During the Study						
n (PP)	24 Hours	48 Hours	72 Hours	96 Hours	120 Hours	Kaplan Meier
SMT % 31 (29)	0 (0)	ITT $P = 0.045$				
ECAD % 39 (33)	13 (15)			58 (64)	61 (67)	72 (74)
						PPP=0.017

Values are percentage of patients reaching a 2-grade improvement at each time after randomization. () represent PP analysis. At any time during the study, patients receiving ECAD achieved a higher response rate than the SMT group.

Predicting the Decrease of Conjugated Bilirubin With Extracorporeal Albumin Dialysis MARS Using the Predialysis Molar Ratio of Conjugated Bilirubin to Albumin

Figure 2. Reduction in conjugated bilirubin as a function of predialysis molar ratio of conjugated bilirubin to albumin. The regression equation is $(12.8 \times \text{predialysis molar ratio of conjugated bilirubin to albumin} - 12.2)$.

Similarities, Differences, and Potential Synergies in the Mechanism of Action of Albumin Dialysis Using the MARS Albumin Dialysis Device and the CytoSorb Hemoperfusion Device in the Treatment of Liver Failure

Fig. 2. Residual levels of water-soluble marker molecules (Cr (a), urea (b), and ammonia (c)) referenced against initial compartment 1 concentrations over time (n = 15, P1, patient 1st).

Fig. 3. Residual levels of albumin-bound marker molecule (bilirubin) referenced against initial compartment 1 concentrations for total bilirubin (a) as well as albumin-bound bilirubin (b) and indirect bilirubin (c) over time (n = 15, P1, patient 1st).

Fig. 4. Residual levels of albumin-bound marker molecules bile acids (chenodeoxycholic acid) **(a)** and bromosal-phthalate (BSP) **(b)** referenced against initial compartment I concentrations over time ($n = 3$). PI, patient inlet.

Fig. 5. Residual levels of IL-6 **(a)** and TNF- α **(b)** referenced against initial compartment I concentrations over time ($n = 11$). IL, interleukin; TNF- α , tumor necrosis factor- α ; PI, patient inlet.

Prometheus from Fresenius

Specifically, the patient's blood first passes through an albumin-permeable biocompatible filter (Albuflow®; molecular weight cutoff of 250kDa), filtering out an albumin rich plasma fraction which then passes through a neutral resin adsorber (Prometh® 01) and an anion-exchanger (Prometh® 02) before being returned to the blood.

The reconstituted blood then undergoes conventional dialysis using a high-flux polysulfone dialyzer.

Reduction in bilirubin and ammonia and improvement in HE and HRS but no outcome benefit.

DIALIVE – combination of Septet and Oxiris

Schematic representation of a prototype of the Dialive LDD system

Randomized, controlled clinical trial of the DIALIVE liver dialysis device versus standard of care in patients with acute-on-chronic liver failure

Graphical abstract

32 pts with alcohol related ACLF.

There were no significant differences in 28-day mortality or occurrence of serious adverse events between the groups.

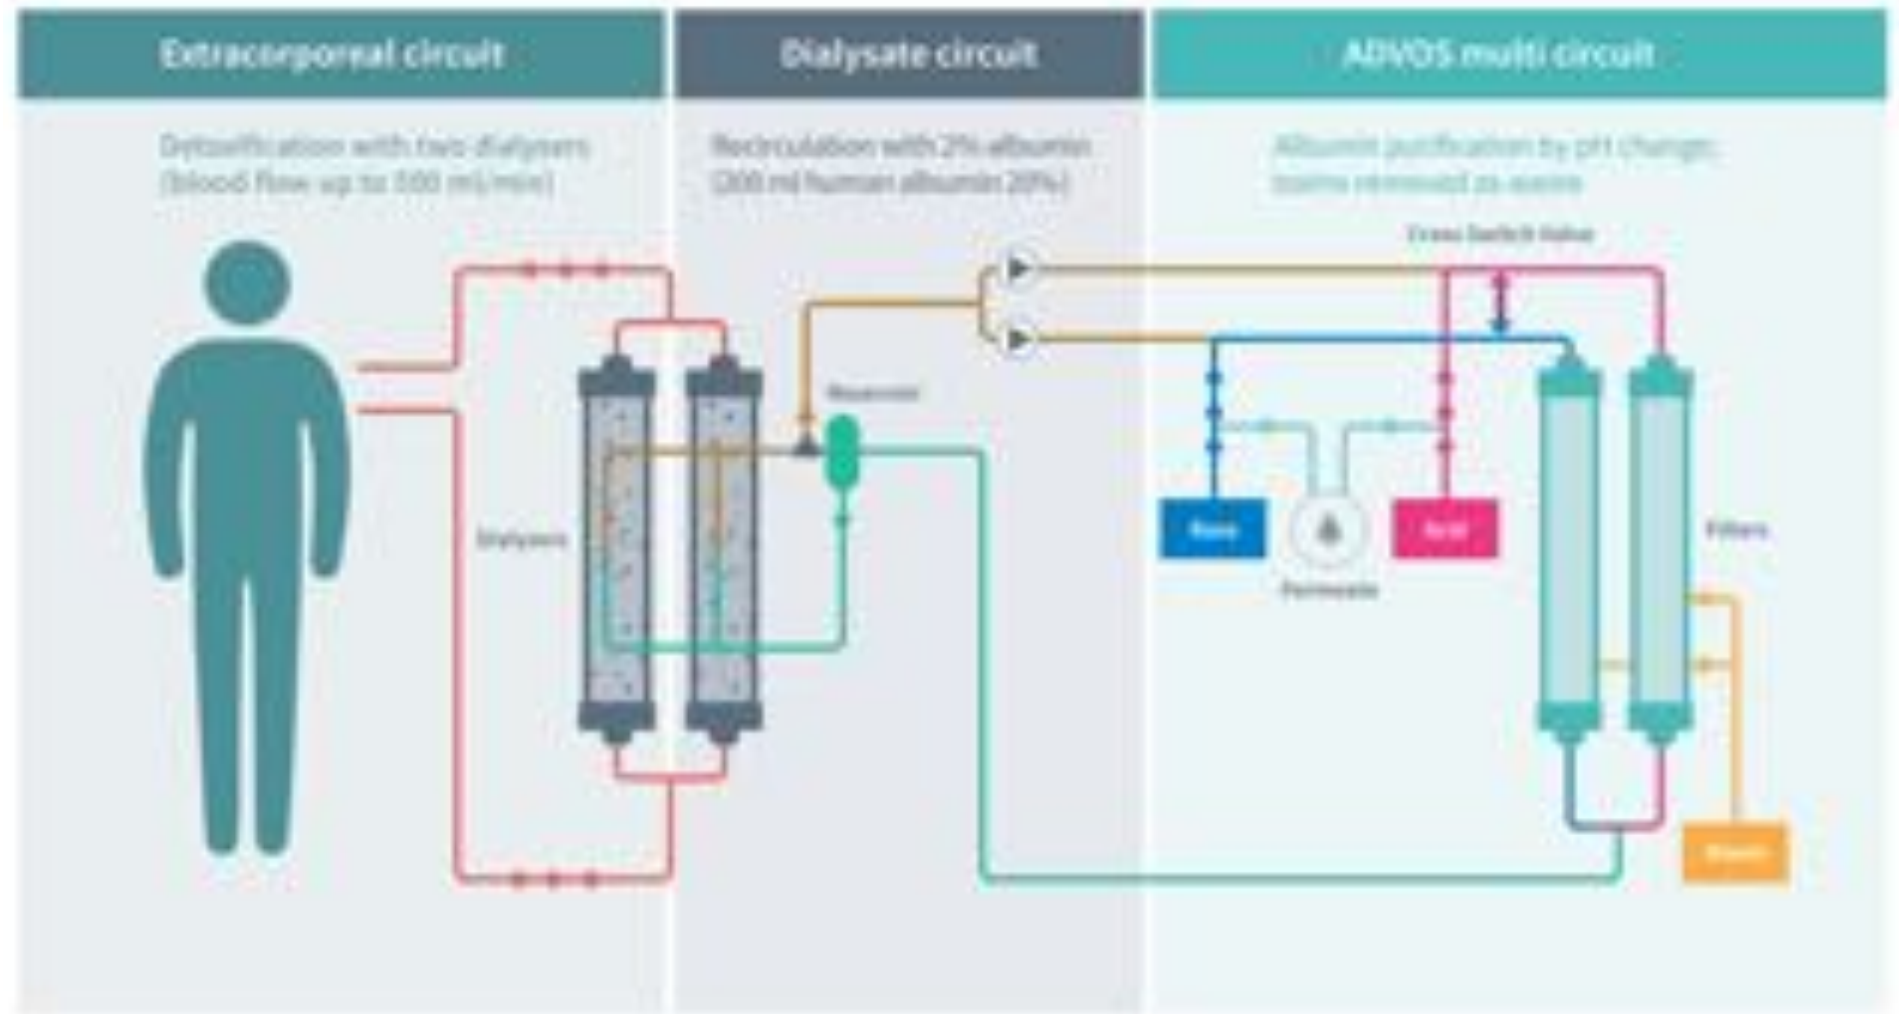

Significant reduction in the severity of endotoxemia and improvement in albumin function was observed in the DIALIVE group, which translated into a significant reduction in the CLIF-C (Chronic Liver Failure consortium) organ failure ($p = 0.018$) and CLIF-C ACLF scores ($p = 0.042$) at Day 10.

Time to resolution of ACLF was significantly faster in DIALIVE group ($p = 0.036$).

Biomarkers of systemic inflammation such as IL-8 ($p = 0.006$), cell death [cytokeratin-18: M30 ($p = 0.005$) and M65 ($p = 0.029$)], endothelial function [asymmetric dimethylarginine ($p = 0.002$)] and, ligands for Toll-like receptor 4 ($p = 0.030$) and inflammasome ($p = 0.002$) improved significantly in the DIALIVE group

Agarwal et al. J Hep 2023

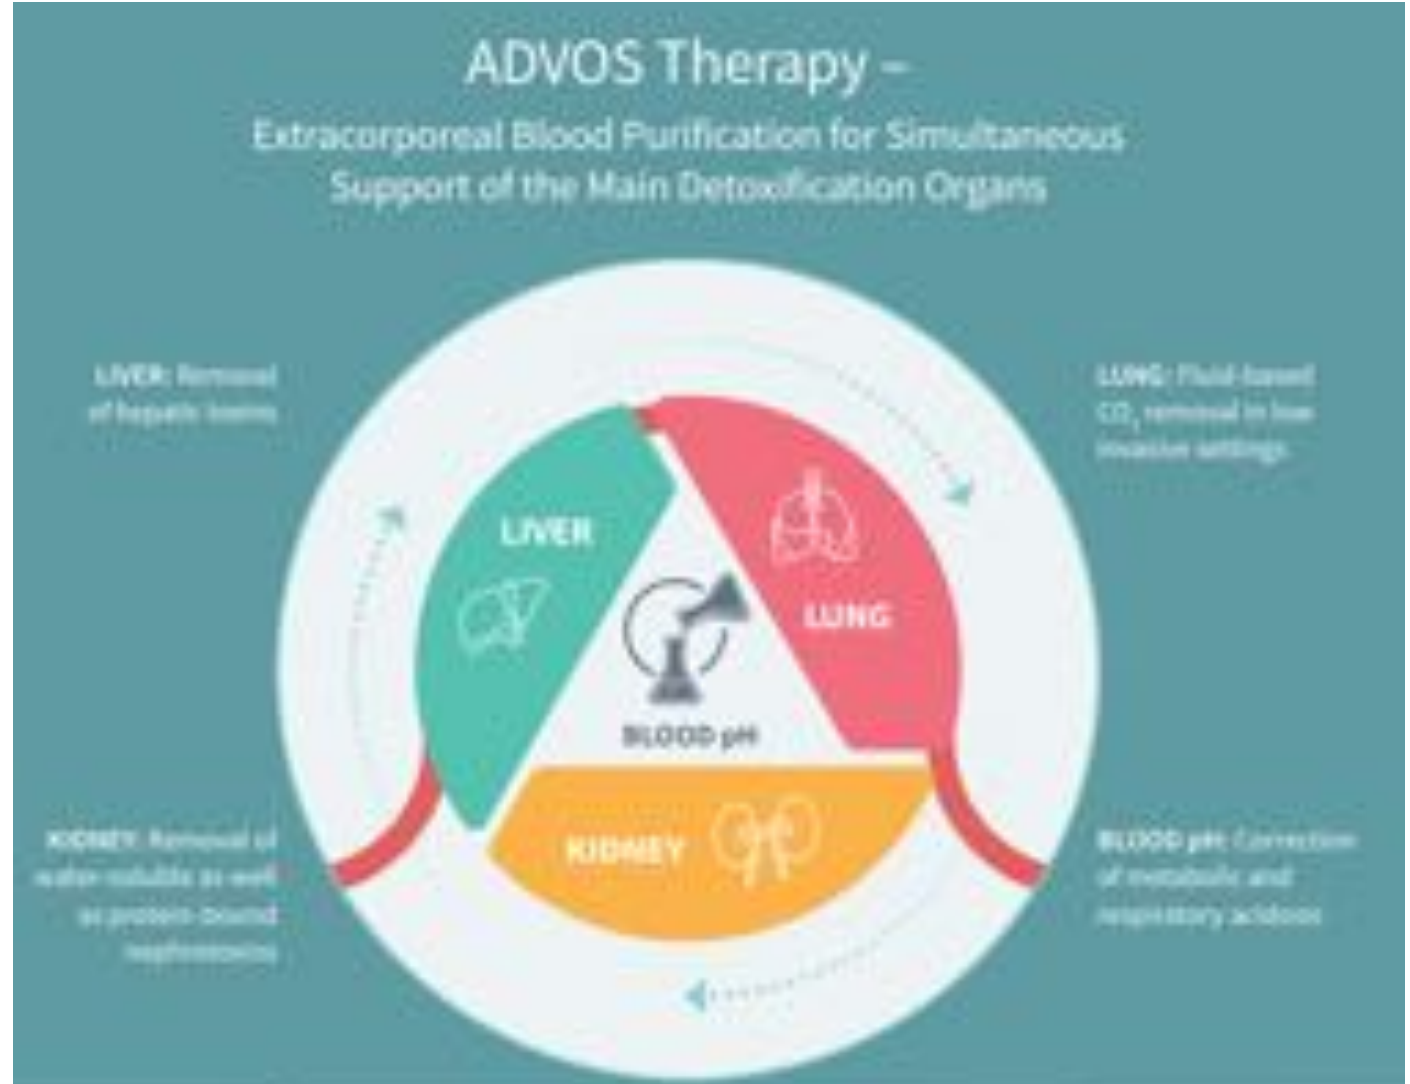

ADVOS

Highest possible detoxification performance:

- Blood pH management (H^+ , HCO_3^-)
- Kidney (water-soluble and protein-bound toxins)
- Liver (protein-bound toxins)
- Lung (CO_2)

The ADVOS procedure (ADVanced Organ Support) provides multi-organ support to the kidneys, liver and lung while simultaneously correcting acid-base disorders in patients.

Successful elimination of bilirubin in critically ill patients with acute liver dysfunction using a cytokine adsorber and albumin dialysis: a pilot study.

Scharf et al. Scientific Reports May 2021

Figure 2. Development and relative reduction in bilirubin levels in patients with Cytosorb® and ADVOS therapy. d-1: day before treatment, d0: directly before treatment, d1: directly after treatment, CS: Cytosorb®, ADV: advanced organ support; orange line represents the median, grey boxes the interquartile range and the whiskers are limited to 1.5 times the interquartile range.

39 patients (33 CS, 6 ADVOS) were included (> 90 minutes of treatment).

The median bilirubin at d0 was 16.9 and 17.7 mg/dl and at d1 was 13.2 and 15.9 mg/dl, in the CS and ADVOS group, respectively.

There was a significant bilirubin reduction as well in the CS group ($p < 0.001$, median relative reduction: 22.5%) as in the ADVOS group ($p = 0.028$, median relative reduction: 22.8%).

Extracorporeal removal

- Bilirubin & bile acids
- Ammonia
- Cytokines
- Endotoxin
- Fluids
- Electrolytes
- Glucose
- Antimicrobials (Antibiotics, antifungals, antivirals) ?? Therapeutic drug monitoring

Prismasol (CRRT replacement fluid) – note possible 0 glucose

Calcium chloride, USP, is chemically designated calcium chloride dihydrate ($\text{CaCl}_2 \cdot 2 \text{H}_2\text{O}$).
Magnesium chloride, USP, is chemically designated magnesium chloride hexahydrate ($\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$).
Dextrose, USP, is chemically designated D-Glucose anhydrous ($\text{C}_6\text{H}_{12}\text{O}_6$) or D-Glucose monohydrate ($\text{C}_6\text{H}_{12}\text{O}_6 \cdot \text{H}_2\text{O}$).
Lactic acid, USP, is chemically designated $\text{CH}_3\text{CH}(\text{OH})\text{COOH}$.
Sodium chloride, USP, is chemically designated NaCl .
Potassium chloride, USP, is chemically designated KCl .
Sodium bicarbonate, USP, is chemically designated NaHCO_3 .

The pH of the final solution is in the range of 7.0 to 8.5.

Solutions in contact with the plastic container can leach out certain of its chemical components in very small amounts within the expiration period, e.g. di 2-ethylhexyl phthalate (DEHP), up to 3 parts per million; however, the safety of the plastic has been confirmed in tests in animals according to USP biological tests for plastic containers as well as by in-vitro toxicity studies.

From: [Drug Dosing in Patients Undergoing Therapeutic Plasma Exchange](#)

	Yes	No	Unclear
Is the volume of distribution (Vd) < 0.2 L/kg?			
Is protein binding (fb) > 80%?			
Is the half-life (t½) > 2h?			
Will TPE start during the distribution phase of the drug OR will the drug be dosed immediately prior to or during TPE ?			
Does the patient have dysfunction of a drug elimination organ?			
Are transient changes in concentration of clinical relevance?			
Is there any new evidence that suggests removal of the drug by TPE?			

- It is likely that some of this drug will be removed with TPE: administer dose after TPE when available; dose supplementation after TPE may be required; use TDM when possible

- It is unlikely that this drug will be removed using TPE: no drug adjustment is required

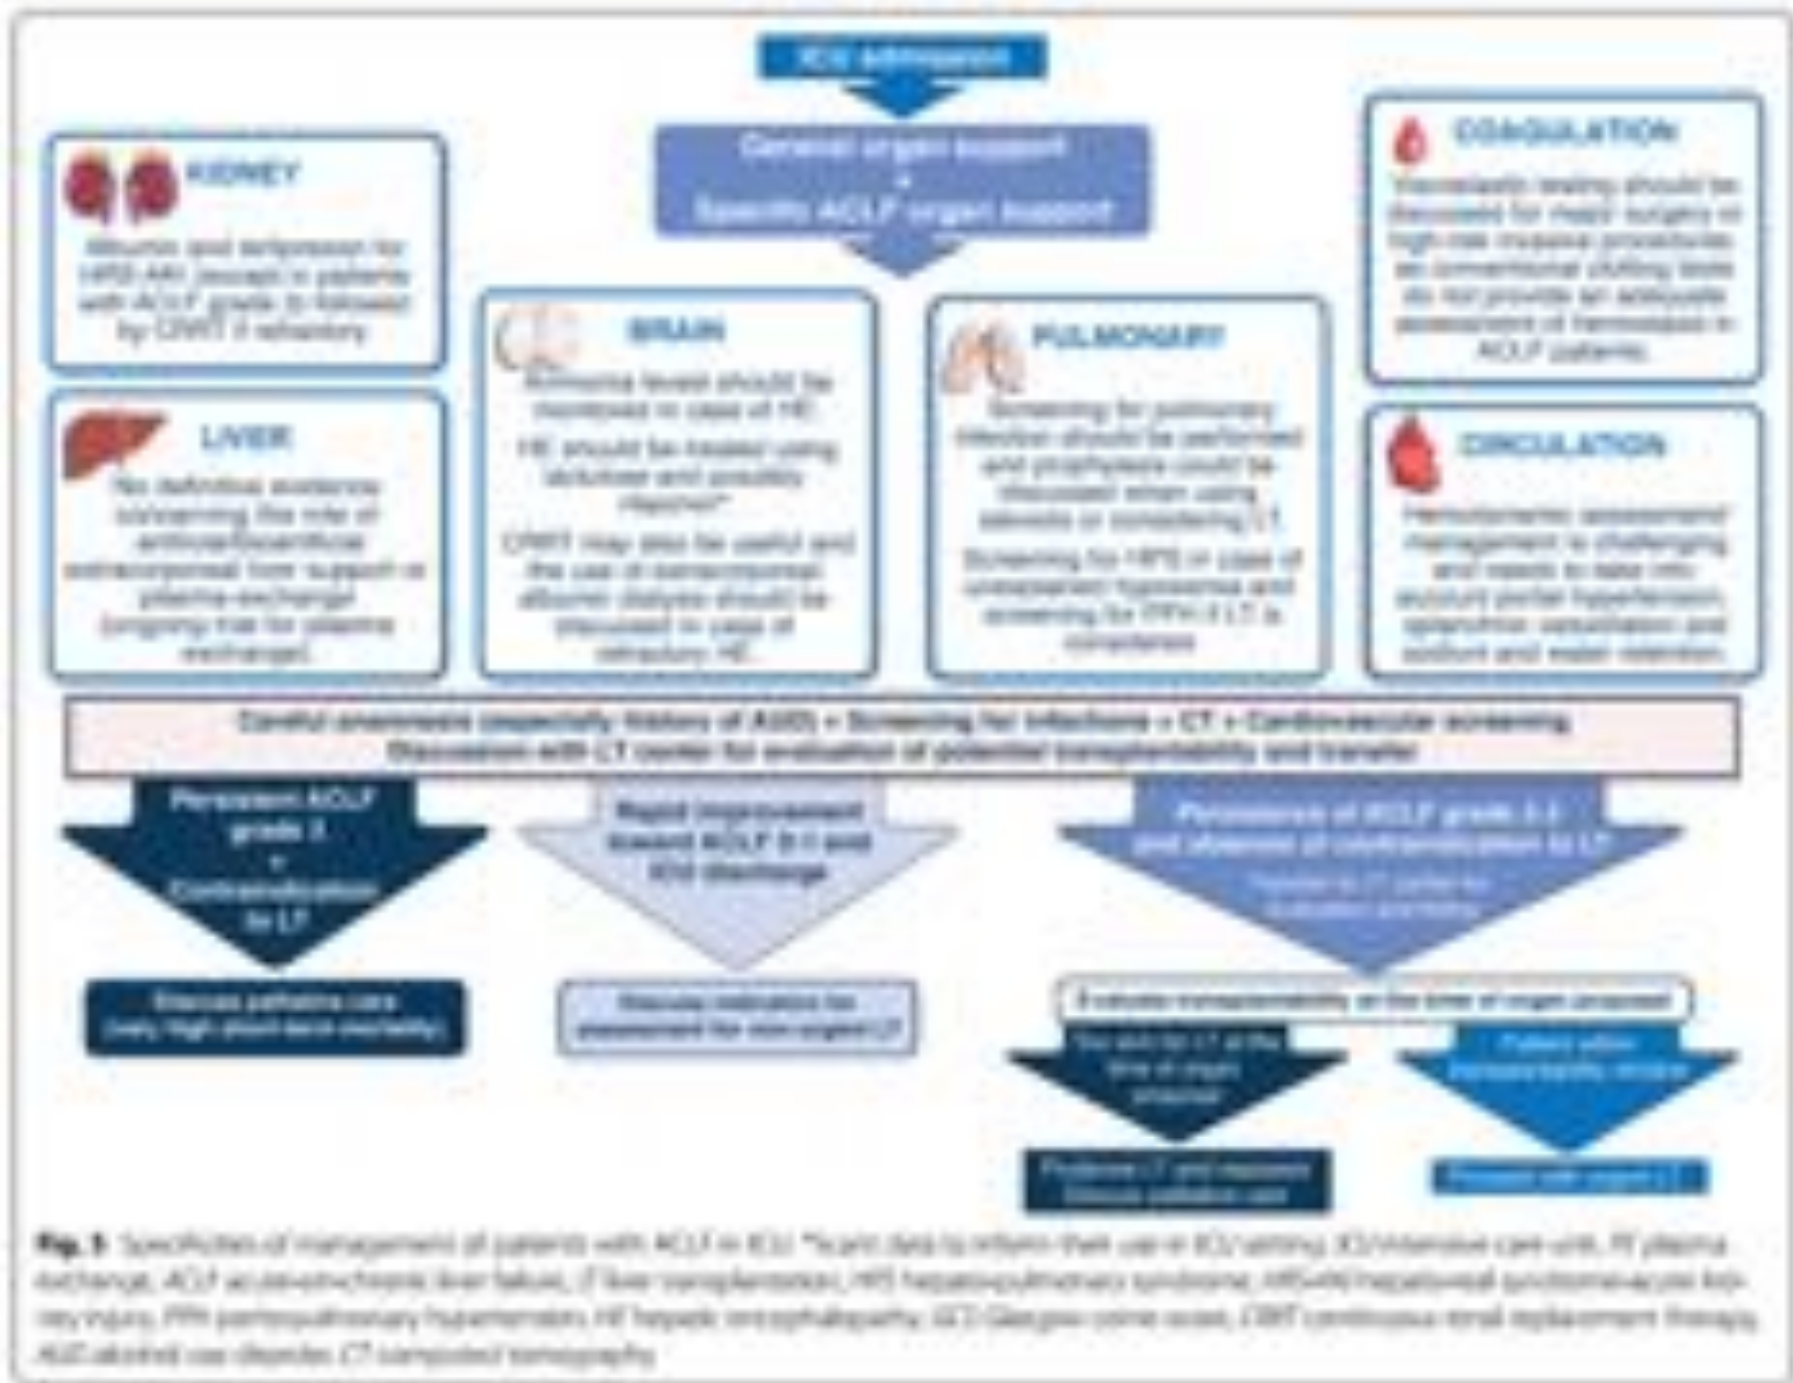

- Use TDM when possible; closely monitor patient for changes in clinical status that could suggest sub-therapeutic drug levels

Checklist to determine how likely drugs are removed by therapeutic plasma exchange (TPE)

Coagulation

- Plasmapheresis has FFP replacement (even up to 10L per day in Larsen study)
- Without plasmapheresis, please adjust support accordingly.
- Otherwise, rapid rise in INR and may result in bleeding.
- Can consider Octaplex (prothrombin complex concentrate - contains freeze dried human derived Factors II, VII, IX, X and Proteins S and C) instead of FFP

Intensive care management of acute on chronic liver failure.

Perricone et al. Intensive Care Med 2023.

Fig. 5 Specificities of management of patients with ACLF in ICU. *Acute data is referred their use in ICU setting. LT=Intensive care unit, PE plasma exchange, ACLF acute-on-chronic liver failure, LT liver transplantability, HPS hepatopulmonary syndrome, OPH (hepatorenal syndrome) acute hep- renal injury, PPH hepatopulmonary hypertension, HE hepatic encephalopathy, CT Glasgow coma score, CRRT continuous renal replacement therapy, ABO alcohol use disorder, CT computed tomography

Liver Transplantation Considerations

- Candidate or not
- Cadaveric vs Live donor options
- Referral to a liver transplant centre for consideration
- Otherwise, palliative care options
- Transplant workup takes time
- Ethics approval (TEC) is required for all live donor liver transplantation
- Urgent transplant listing (criteria)
- Extracorporeal support while waiting for Ltx ?? Indications for starting (HRS, HE, or biochemical). Goals of care ?

Important points to consider for Plasmapheresis

- Transplant vs non transplant candidate
- Timing of transplant
- Patient factors: Cerebral oedema/ hepatic encephalopathy, renal failure plus electrolyte issues
- Dose / volume (30 litres in 3 days or 5 litres or 3.5 litres) of PE
- Filtration based or Centrifugation based
- Replacement (Fresh frozen plasma) strategy
- Intermittent therapy – daily or spaced
- Additional extracorporeal interventions (MARS, CRRT or hemoperfusion)

Plasma Exchange in Acute and Acute on Chronic Liver Failure.

Maiwall and Sarin. Semin in Liver Dis 2021.

Table 3 The techniques of therapeutic plasma exchange (TPE)

	Technique of TPE	
	Filtration based	Centrifugation based
Blood flow rate (ml/h)	150–200	50
Filtration fraction (%)	~30	~80
Technique	Membrane which separates the cellular from acellular components	Centrifugal force of blood rotation separates the cellular from the acellular components based on the specific gravity
Time	Slower	Faster clearance achieved in one-third of time
Pumping (min)	~23–40	~11
Procedure time (min)	~130–160	~81–120
Plasma removal efficiency (%)	Less efficient 27–53	More efficient 80–93
Anticoagulation	Usually heparin based	Citrate based

Note: Adapted from references.^{102–114}

Anticoagulation for extracorporeal circuit

- None – high INR (? Viscoelastic)
- Heparin priming alone
- Continuous heparin (target PTT or ACT)
- Citrate (accumulation with liver failure)
- Higher blood flow
- Prefilter fluid replacement
- Adsorption cartridge ?

Conclusions

- Severe ACLF (high CLIF-C ACLF score) needs **urgent liver transplantation**
- Extracorporeal liver support systems (non biological) currently have NO demonstrated survival advantage to SMT
- Removal of “hepatotoxins” can be achieved
- Removal of “cytokines” can be achieved
- Improvement in HE (clinical) can be aided by extracorporeal liver support
- **Combination of modalities** should be studied further
- CRRT plus/minus additional adsorption cartridge is available in most ICUs – just ensure appropriate clearance (**DOSE**)
- Be cautious of removing “goodies” (anti-infectives)
- Value proposition ????

“ The original phrase is
God is in the details. ”

Small things matter in critically ill patients.

Continuous and meticulous care with a team of professionals working together creates the final tapestry of success.

One note does not make a symphony; one artist does not make an orchestra.

Plasma exchange for acute and acute-on-chronic liver failure: A systematic review and meta-analysis

Beran et al. Liver Transpl. 2023 Aug 3.

- In conclusion, PE is associated with improved survival in ALF and could improve survival in ACLF.
- PE may be considered in managing ALF and ACLF patients who are not liver transplant (LT) candidates or as a bridge to LT in otherwise eligible patients.
- Further randomized controlled trials are needed to confirm the survival benefit of PE in ACLF.
